Package 'nplr'

October 13, 2022

Type Package

Title N-Parameter Logistic Regression

Version 0.1-7

Date 2016-12-25

Maintainer Frederic Commo <fredcommo@gmail.com>

Depends methods

Imports stats,graphics,utils

Suggests RUnit,knitr

VignetteBuilder knitr

Description Performing drug response analyses and IC50 estimations using n-Parameter logistic regression. Can also be applied to proliferation analyses.

R topics documented:

convertToProp *Function to Convert a Vector Into Proportions.*

Description

Convert a vector of values to proportions, given a minimun and a maximun value (optional). See Details and Examples.

Usage

```
convertToProp(y, T0 = NULL, Ctrl = NULL)
```

Arguments

y	: a vector of values (responses to x).
T0	: the minimal value to consider. If NULL (default), min(y, na.rm=TRUE) will be used. See Details and Warning.
Ctrl	: the maximal value to consider. If NULL (default), max(y, na.rm=TRUE) will be used. See Details and Warning.

Details

In typical cell viability experiments, responses to drug concentrations (inhibition rate) may be estimated with respect to a time zero (T0) and an untreated condition values (Ctrl), as described in [1]:

If none of the T0 and Ctrl values are provided, min(y, na.rm=TRUE) and max(y, na.rm=TRUE) will be used, respectively. See Warning.

Value

a vector of values.

Warning: Note that, for drug response analyses, rescaling the responses between 0 to 1 using to the min and max of y, would lead to estimate a EC50 (the half effect between the maximum and the minimum of the observed effects), rather than a IC50.

Note

The data used as examples come from the NCI-60 Growth Inhibition Data: https://wiki.nci.nih.gov/display/NCIDTPdata/NCI-60+Growth+Inhibition+Data, except for multicell.tsv which are simulated data.

Examples

```
## Using the MDA-N data
  op <- par(no.readonly=TRUE)         # save default parameters

  require(nplr)
  path <- system.file("extdata", "mdan.txt", package = "nplr")
  mdan <- read.delim(path)

# fit a model on the original responses (proportions of control):
  conc <- mdan$CONC
  y0 <- mdan$GIPROP
  model0 <- nplr(conc, y0)

# Adjust the data between 0 to 1, then fit a new model:
  y1 <- convertToProp(y0)
  model1 <- nplr(conc, y1)

  par(mfrow=c(1, 2))
  plot(model0, ylim = range(0, 1), main = "Original y values")
  plot(model1, ylim = range(0, 1), main = "Rescaled y values")
  par(op)
```

`getEstimates` *Function to Estimate x Given y.*

Description

This function takes as its first argument a model returned by `nplr()`. By inverting the logistic model, it estimates the x values corresponding to one (or a vector of) y target(s) provided. The standard error of the model, defined as the mean squared error on the fitted values, is used to estimate a confidence interval on the predicted x values, according to the specified `conf.level`. see `Details`.

Usage

```
  ## S4 method for signature 'nplr'
getEstimates(object, targets = seq(.9, .1, by = -.1), B = 1e4, conf.level = .95)
```

Arguments

`object`	: an object of class `nplr`.
`targets`	: one, of a vector of, numerical value(s) for which the corresponding x has to be estimated. Default are target values from .9 to .1.
`B`	: the length of the y distribution from which the x confidence interval is estimated.
`conf.level`	: the estimated x confidence interval, bounded by (1-conf.level)/2 and 1 - (1-conf.level)/2 (by default .95, which gives x.025 and x.975).

Details

In n-parameter logistic regressions, none of the parameters follow any particular distribution from which confidence intervals can be estimated. To overcome this issue, the standard error is used to generate a normal distribution of the target(s) passed to the function. The quantiles of that distribution are used in order to provide estimated bounds for the corresponding x value, with respect to `conf.level`. See also `Warning`.

Value

A data set containing:

`y`	: the target value.
`x.05`	: the lower bound of the estimated 95% confidence interval (default). If another value is passed to conf.level, x will be labelled as x.(1-conf.level)/2.
`x`	: the estimated value.
`x.95`	: the upper bound of the estimated 95% confidence interval (default). If another value is passed to conf.level, x will be labelled as x.1-(1-conf.level)/2.

Warning: Notice that, if any $target <= B$ or $target >= T$, in other words outside the 2 asymptotes, the maximal (or minimal) possible value the model can estimates is returned.

Note

The data used in the examples are samples from the NCI-60 Growth Inhibition Data: https://wiki.nci.nih.gov/display/NCIDTPdata/NCI-60+Growth+Inhibition+Data, except for multicell.tsv which are simulated data.

# Using the PC-3 data
  require(nplr)
  path <- system.file("extdata", "pc3.txt", package="nplr")
  pc3 <- read.delim(path)
  model <- nplr(x = pc3$CONC, y = pc3$GIPROP)
  getEstimates(model)
  getEstimates(model, c(.3, .6), conf.level = .9)
```

---

nplr *Function to Fit n-Parameter Logistic Regressions.*

Description

This function computes a weighted n-parameters logistic regression, given x (typically compound concentrations) and y values (responses: optic densities, fluorescence, cell counts,...). See `Details`.

Usage

```
nplr(x, y, useLog = TRUE, LPweight = 0.25, npars = "all",
        method = c("res", "sdw", "gw"), silent = FALSE)
```

Arguments

`x`	: a vector of numeric values, e.g. a vector of drug concentrations.
`y`	: a vector of numeric values, e.g. a vector of responses, typicaly provided as proportions of control.
`useLog`	: Logical. Should x-values be Log10-transformed. Default to `TRUE`, set to `FALSE` if x is already in Log10.
`LPweight`	: a coefficient to adjust the weights. $LPweight = 0$ will compute a non-weighted np-logistic regression.
`npars`	: a numeric value (or `"all"`) to specify the number of parameters to use in the model. If `"all"` the logistic model will be tested with 2 to 5 parameters, and the best option will be returned. See `Details`
`method`	: a character string to specify what weight method to use. Options are `"res"(Default)`, `"sdw"`, `"gw"`. See `Details`
`silent`	: Logical. Specify whether `warnings` ad/or `messages` has to be silenced. Default to `FALSE`.

Details

The 5-parameter logistic regression is of the form:

$$y = B + (T - B)/[1 + 10^{(}b * (xmid - x))]^s$$

where B and T are the bottom and top asymptotes, respectively, b and xmid are the Hill slope and the x-coordinate at the inflexion point, respectively, and s is an asymetric coefficient. This equation is sometimes refered to as the Richards' equation [1,2].

When specifying npars = 4, the s parameter is forced to be 1, and the corresponding model is a 4-parameter logistic regression, symetrical around its inflexion point. When specifying npars = 3 or npars = 2, add 2 more constraints and force B and T to be 0 and 1, respectively.

Weight methods:

The model parameters are optimized, simultaneously, using nlm, given a sum of squared errors function, sse(Y), to minimize:

$$sse(Y) = \Sigma[W.(Yobs - Yfit)^2]$$

where Yobs, Yfit and W are the vectors of observed values, fitted values and weights, respectively.

In order to reduce the effect of possible outliers, the weights can be computed in different ways, specified in nplr:

- residual weights, "res":
$$W = (1/residuals)^L Pweight$$
where residuals and LPweight are the squared error between the observed and fitted values, and a tuning parameter, respectively. Best results are generally obtained by setting $LPweight = 0.25$ (default value), while setting $LPweight = 0$ results in computing a non-weighted sum of squared errors.
- standard weights, "sdw":
$$W = 1/Var(Yobs_r)$$
where Var(Yobs_r) is the vector of the within-replicates variances.
- general weights, "gw":
$$W = 1/Yfit^L Pweight$$
where Yfit are the fitted values. As for the residuals-weights method, setting $LPweight = 0$ results in computing a non-weighted sum of squared errors.

The standard weights and general weights methods are describes in [3].

Value

An object of class nplr.

slots

- x : the x values as they are used in the model. It can be Log10(x) if useLog was set to TRUE.
- y : the y values.
- useLog : logical.
- npars : the best number of parameters if npars="all", the specified number of parameters, otherwise.
- LPweight : the weights tuning parameter.

- yFit : the y fitted values.
- xCurve : the x values generated to draw the curve. 200 points between the `min` and `max` of `x`.
- yCurve : the fitted values used to draw the curve. the fitted values corresponding to `xCurve`.
- inflPoint : the inflexion point x and y coordinates.
- goodness : the goodness-of-fit. The correlation between the fitted and the observed y values
- stdErr : the mean squared error between the fitted and the observed y values
- pars : the model parameters.
- AUC : the area under the curve estimated using both the trapezoid method and the Simpson's rule.

Note

The data used in the examples are samples from the NCI-60 Growth Inhibition Data: https://wiki.nci.nih.gov/display/NCIDTPdata/NCI-60+Growth+Inhibition+Data, except for multicell.tsv which are simulated data.

nplrAccessors — nplr *accessor functions*

Description

Methods for extracting information from an object of class nplr. Each of the below methods are simply convenience functions which extract the corresponding slots (as the name of each method suggests) from the object of class nplr.

Methods

signature(object = "nplr")

- getX(object)
- getY(object)
- getXcurve(object)
- getYcurve(object)
- getFitValues(object)
- getInflexion(object)
- getPar(object)
- getAUC(object)
- getGoodness(object)
- getStdErr(object)
- getWeights(object)

See Also

nplr, getEstimates

overlay — *Plotting Multiple* nplr *Objects*

Description

To superimpose multiple logistic models fitted using nplr.

Usage

```
overlay(modelList = NULL, showLegend = TRUE, Cols = NULL, ...)
```

Arguments

modelList	: list. A list of objects of class nplr.
showLegend	: logical. Whether the legend has to be displayed.
Cols	: character. A vector of colors to use. If NULL (default), greys will be used.
...	: Other graphical parameters. See par.

Examples

```
path <- system.file("extdata", "multicell.tsv", package="nplr")
multicell <- read.delim(path)

# Computing models (to store in a list)
cellsList <- split(multicell, multicell$cell)
Models <- lapply(cellsList, function(tmp){
  nplr(tmp$conc, tmp$resp, silent = TRUE)
  })

# Visualizing
overlay(Models, xlab = expression(Log[10](Conc.)), ylab = "Resp.",
  main="Superimposing multiple curves", cex.main=1.5)
```

---

plot.nplr *Plotting* nplr *Objects*

Description

This function allows visualizing logistic models fitted using nplr.

Usage

```
  ## S3 method for class 'nplr'
plot(x, pcol = "aquamarine1", lcol = "red3",
  showEstim = FALSE, showCI = TRUE, showGOF = TRUE, showInfl = FALSE,
  showPoints = TRUE, showSDerr = FALSE, B = 1e4, conf.level = .95, unit = "", ...)
```

Arguments

x	: an object of class nplr
pcol	: the points color.
lcol	: the line color.
showEstim	: logical/numeric. If a numerical value is passed (a y value to reach), the estimated x value , and interval, is displayed on the plot. Default is FALSE
showCI	: logical. show the estimated confidence interval
showGOF	: logical. show the estimated goodness-of-fit.
showInfl	: logical. add the inflexion point on the plot.
showPoints	: logical. add the points on the plot.
showSDerr	: logical. add the standard errors on the plot (maybe useful in case of experiment with replicates).
B	: the length of simulated y values. Used to estimate the confidence interval
conf.level	: the confidence level. See getEstimates
unit	: the unit to specify when showEstim is TRUE. Default is an empty string.
...	: other graphical parameters. See par.

  plot(model, showEstim = 0.5, unit = "nM")
```

summary.nplr *summaryzing* nplr *Objects*

Description

A S3 method to visualize a model summary as a table.

Usage

```
  ## S3 method for class 'nplr'
summary(object, ...)
```

Arguments

object	: an object of class nplr
...	: other optional parameters (not used).
